METHOD OF ANALYSIS

DETERMINATION OF STERENES IN REFINED
VEGETABLE OILS

1. PURPOSE

Determination of sterenes (campestadienes and stigmastadienes), hydrocarbons originated from sterols during refining or desterolizing treatments applied to vegetable oils.

2. SCOPE

The standard may be used to detect desterolized seed oils in refined olive oil, refined olive residue oil and admixtures of these oils with virgin olive oil. The procedure may be also used to quantify stigmastadienes in oils where they occur at a concentration greater than 4.0 mg/kg.

3. PRINCIPLE

Isolation of steroidal hydrocarbon fraction by column chromatography on silica gel impregnated with silver nitrate, and analysis by capillary gas chromatography.

4. APPARATUS

4.1. 100 mL Round-bottomed flasks.

4.2. 500 mL Round-bottomed flasks.

4.3. 25 mL Erlenmeyer flasks.

4.4. Desiccator containing activated silica gel.

4.5. Rotary evaporator.

4.6. Glass chromatography column (1.5-2.0 cm i.d. by 50 cm length) with Teflon tap and a plug of glass wool fibre or sintered glass disc at the bottom. To prepare silica gel column, pour hexane into the column to a depth of approximately 5 cm and then fill with a slurry of argentated silicagel (5.5) in hexane (20 g in 40 mL) with the help of hexane portions. Allow to settle and finish settling by applying slight vibration. Add anhydrous sodium sulphate to a height of approximately 0.5 cm, finally elute the excess hexane.
4.7. Gas chromatography with flame ionization detector, split injector (or cold on-column) and oven programable to within ±1 °C.

4.8. Fused silica capillary column for gas chromatography (0.25 mm i.d. by 25 m length) coated with 5%-phenylmethylsilicone phase, 0.25 μm film thickness.

**Note 1** Other columns of similar or lower polarity can be used.

4.9. Integrator-recorder with possibility of valley-valley integration mode.

4.10. 5-10 μL Microsyringe for gas chromatography with cemented needle.

5. **REAGENTS**

All the reagents should be of analytical grade unless otherwise specified. The water used should be distilled water, or water of at least equivalent purity.

In order to check the purity of the reagents, a blank assay should be done.

5.1. Hexane or mixture of alkanes of b.p. interval 65-70 °C, distilled with rectifying column.

5.2. Silver nitrate.

5.3. Anhydrous sodium sulphate.

5.4. Silica gel 60 for column chromatography, 70-230 mesh, (Merck ref. 7734 or similar), heated in oven at 110 °C during two or more hours and allow to cold in desiccator (4.4).

5.5. Preparation of argentated silica gel for two columns.

In a 500 mL round-bottom flask (4.2), weigh 30 g of activated silica gel (5.4). In a 25 mL erlenmeyer flask (4.3), dissolve 3.0 g of silver nitrate in 7 mL of distilled water, and with a pipette add drop by drop the solution on the silica gel shaking from time to time. Put the stopper on the flask and shake vigorously for 20 s, place the flask in the rotary evaporator and rotate for 30 min under atmospheric pressure and room temperature. The silica gel turns lightly grey and can be kept in stoppered flask in darkness.

5.6. Stock solution (200 ppm) of cholesta-3,5-diene (Sigma) in hexane (10 mg in 50 mL).

5.7. Standard solution of cholesta-3,5-diene in hexane at a concentration of 20 ppm, obtained by dilution of above solution.

**Note 2** If kept at under 4 °C, solutions 5.6 and 5.7 will not deteriorate over a period of at least 4 months.

5.8. Solution of n-nonacosane in hexane at concentration approx. 100 ppm.

5.9. Carrier gas for chromatography: helium or hydrogen of 99.9990% purity.

5.10. Auxiliary gases for flame ionization detector: hydrogen of 99.9990% purity and purified air.
6. PROCEDURE

6.1.1. Weigh 1 ± 0.01 g of oil in a 10 mL beaker, add 1 mL of standard solution of cholesta-3,5-diene (20 µg), take the mixture to the fractioning column with the aid of two 1 mL portions of hexane and run the sample onto the column by allowing the solution level to drop to the top of the sodium sulphate.

6.1.2. Start the chromatographic elution with hexane at a flow rate of 1 mL/min approx. Discard the first 40 mL of elution and then collect the next 60 mL and, separately, the following 20 mL.

Note 3 Optimization of the volumes of the first and second fractions can be done by examination of the gas chromatograms obtained from each fraction. The first fraction must contain saturated hydrocarbons, and does not contain cholestadiene; the second fraction must show steroidal hydrocarbons but not saturated ones and the third fraction should not contain sterenes (Figure 1).

Note 4 At the end of the chromatographic process, the column should be drained and the dry argentated silica gel poured into a container and stored for silver recycling.

6.1.3. Transfer the second fraction to a 100 mL round-bottomed flask (4.1) and evaporate in a rotary evaporator at 30 °C under reduced pressure until dryness and immediately dissolve the residue in 0.2 mL of hexane. Keep the solution in the refrigerator until analysis.

Note 5 The residue (6.1.3) should not be kept dry at room temperature. As soon as it is obtained, the solvent should be added and the solutions should be kept in the refrigerator.

6.2. Gas chromatography.

6.2.1. Working conditions for split injector.

- Injector temperature: 300 °C.
- Detector temperature: 320 °C.
- Oven programming temperatures: initial 235 °C for 6 min and then rising at 2 °C/min up to 285 °C.
- Split injector with 1:15 flow divider.
- Amount of solution injected 2 µL.
- Sensitivity: about 16 times the minimum attenuation.
- Gas carrier: helium or hydrogen at about 120 and 80 kPa of pressure, respectively.
- Integrator-recorder. The parameters for integration should be fixed so as to give a correct assessment of the areas.

These conditions should be adjusted in accordance with the characteristics of the chromatography and the column to give chromatograms meeting the following
requirements: internal standard peak should appear within approx. ± 3 min of the time given in 6.2.2; the internal standard peak should be at least 80% of the full scale.

The gas chromatographic system must be checked injecting a mixture of the stock solution of cholesta-3,5-diene (5.6) and n-nonacosane solution (5.8). The cholesta-3,5-diene peak must appear as a resolved peak just before the n-nonacosane (Figure 2); if it does not occur two actions can be undertaken: change the oven temperature and/or use a less polar column. Under these conditions, the peaks of saturated hydrocarbons do not interfere the sterene peaks (Figure 2).

6.2.2. Peak identification.

Using helium as carrier gas, the internal standard peak appears at approx. 19 min and that of the stigmasta-3,5-diene at relative retention time of approx. 1.28 (Figure 1b). The campesta-3,5-diene appears at retention time of approx. 1.15 relative to standard and approx. 0.90 relative to stigmasta-3,5-diene.

Using hydrogen as carrier gas, the internal standard peak appears at approx. 15 min and that of the stigmasta-3,5-diene at relative retention time of approx. 1.33. The campesta-3,5-diene appears at retention time of approx. 1.18 relative to standard and approx 0.88 relative to stigmasta-3,5-diene.

Campesta-3,5-diene and stigmasta-3,5-diene could occur with small quantities of the respective 2,4-isomers. Usually, the two groups of compounds elute together as two chromatographic peaks. Nevertheless, if the column is too polar or shows a high resolving power, the 2,4-isomer can appear as small peaks before and close to those of respective 3,5-isomers (Figure 3). In order to ensure that the stigmastadienes are eluted as a single peak, it is advisable to replace the column by one which is either less polar or has a wider internal diameter.

Note 6 Gas chromatographic references of these steroidal hydrocarbons can be obtained by analysing samples of refined palm or sunflower oils or of sunflower oil heated with 10% v/w of sulphuric acid:water (1:1) at 150 °C for 5 min.

6.2.3. Quantitative analysis.

The content in stigmastadienes is determined according to the formula:

\[
\text{mg/kg of stigmastadienes} = \frac{A_s \times M_c}{A_c \times M_o}
\]

where: 

- \(A_s\) : area of peak corresponding to stigmastadienes.
- \(A_c\) : area of internal standard
- \(M_c\) : mass of standard added, in micrograms.
- \(M_o\) : mass of oil taken, in grams.
The ratios between the hydrocarbons are calculated as follows:

\[
R_1 = \frac{\text{area of stigmastadienes peak}}{\text{area of campestadienes peak}}
\]

Usually each pair of isomers originates a single chromatographic peak, but if the two isomers yield separated peaks, both areas have to be summed.

The ratios are valid only if the stigmastadiene peaks reaches at least 50% of the full scale.

**Note 7** If the quantity of stigmastadienes is greater than 50 ppm, the analysis should be repeated using a smaller oil sample, inorder to obtain a more exact quantification.
Figure 1. Gas chromatograms of 1st and 2nd fractions obtained on a capillary column (0.25 mm i.d. by 25 m length) coated with 5%-phenylmethylsilicone (0.25 μm film thickness) using helium as gas carrier.

a). 1st Fraction from an olive oil sample
b). 2nd Fraction from a groundnut oil sample
Figure 2. Gas chromatogram of 1st + 2nd fraction obtained from a mixture of refined olive oil and sunflower desterolised oil on a capillary column (0.25 mm i.d. by 25 m length) coated with 5%-phenylmethylsilicone (0.25 μm film thickness) using helium as gas carrier.
Figure 3. Gas chromatogram of the second fraction of palm oil sample, obtained on a polar column (65%-phenylmethylsilicone) showing the sterene isomers.
The precision values have been calculated from the data for 2000–2017 supplied by the laboratories of many countries for earning entitlement under the IOC recognition scheme. The results underwent statistical analysis according to ISO 5725 “Accuracy (trueness and precision) of measurement methods and results” and with the aid of the AOAC Statistical Manual (W.J. Youden, E.H. Steiner). Outliers were detected by applying the Ranking, Cochran and Grubbs tests to the laboratory results for all the samples (replicates a and b).

The table reports the following data for each parameter studied:

- **n**: number of laboratories which participated in the test
- **outliers**: number of laboratories with outlying values
- **mean**: mean of the accepted results
- **r**: repeatability
- **Sr**: repeatability standard deviation
- **RSD_r(%)**: repeatability coefficient of variation (Sr x 100/ mean)
- **R**: reproducibility
- **Sr**: reproducibility standard deviation
- **RSD_r(%)**: reproducibility coefficient of variation (Sr x 100/ mean)
